$\mathrm{C}\mu\mathrm{LOG}$ Project Final Report

An Entity Interaction Simulation Language

John Demme (jdd2127) Nishant Shah (nrs2127) Devesh Dedhia (ddd2121) Cheng Cheng (cc2999)

Columbia University

December 17, 2008

1 Introduction: $C\mu LOG$

 $C\mu LOG$ is a logic language designed for entity interaction simulation. It uses a brute force method for solution searching similar to Prolog but uses a syntax similar to C, making it easier on the typical programmer's eyes, and is compatible with some code tools, such as code indenters and Emacs's c-mode.

Simulations in $C\mu$ LOG involve a set of entities written in $C\mu$ LOG which interact in the simulator. The "environment" entity defines the board on which the "agents" play, and defines the game which the entities play. It is a turn-based simulation during which each agent can look at the contents of the environment and decide which which direction it should move. During this decision, the agents can modify their own working memory, thus affecting their decision for the next turn.

Additionally, the $C\mu$ LOG interpreter may be invoked separately from the simulator. The stand-alone interpreter searches for all the solutions for "main", but typically the output of these programs will be from "print" directives specified in the program.

1.1 Application & Features

One uses the language to provide a set of facts and rules, and the program is run by asking a question, which the interpreter attempts to answer using inferences based on the fact and rule set. $C\mu LOG$ is designed for simulation, so typically a simulator will ask a given agent program what its next action will be. The agent program then uses $C\mu LOG$ s entity interaction features to gather information about its environment and decide what to do. Each agent program can communicate with other programs to find out more information about other agents or its own status in the environment. The simulator stores all the contextual information pertaining to the environment and all of the agents present.

As this language is going to be used for simulating real life agents, we strongly emphasize that the program learn and forget data/rules/information at run-time. For this, similar to "assert" and "retract" of Prolog we have introduced two directives called "learn" and "forget." In $C\mu LOG$ there exist no specific data structures like you would see in Java or Python, however rules and facts can be added to the program dynamically, which allows programs to remember data in a much more natural way since the data simply becomes part of the running code.

The simulator discussed could be modified to be used in other with other simulation environments, such as in a three-dimensional grid simulation with several agents—such as a flight simulation. Alternatively, the interpreter could be used in a real environment like the movement of pick and place robots in a warehouse. The language could be used to define the warehouse environment and agent programs for robots, and a replacement for the simulator would feed live information in to the programs in the form of facts, similarly to how the simulation feeds its state information to agents now.

1.2 Goals

The language and simulator presented here attempts to fulfill the following requirements:

Generic Games are defined mostly by the environment application.

Composable Individual behaviors can be written simply and easily, then combined to obtain high-level actions and reasoning

Declarative Programmers can specify what they want entities to do rather than how

Controlled Communication Data in the system is frequently made up of nearly-atomic bits of data many of which can be used both on their own and composed as complex data. This means that subsets and smaller pieces of data can be communicated between entities without loosing meaning.

High-level libraries Due to the flexibility and composibility of the language, high-level algorithms-such as path finding-can be easily implemented in libraries, allowing further, domain-specific intelligence to be written in the programs.

2 Tutorial

Logic programming is a kind of computer programming using mathematical logic. Specifically, it is based on the the idea of applying a theorem-prover to declarative sentences and deriving implications. Compared with procedural languages, logic programming solves the problem by setting rules with which solutions must fit. We can represent logic programming by the formula:

```
Facts + Rules = Solutions
```

Logic programming languages are inherently high level languages, allowing programmers to specify problems in a declarative manner, leaving some or all of the details of solving the problem to the interpreter.

Both the programming and data structures in both prolog and $C\mu LOG$ can be very simple- such as facts. The relationship between code and data is also of note. $C\mu LOG$ uses the Von Neumann style (vs. Harvard architecture) wherein data is code. It is therefore possible (and inherently necessary) for programs to be introspective and self-modifying. In other words, it is easier for programs to learn and adapt.

2.1 Variables

Variables represent a value to be solved for. They don't have a fixed datatype, but match to the refered type. All variables are scoped to the rule, so that variable solutions can be shared between sub-blocks.

Variables are represented by a dollar sign (\$) then the variable name. The name must start with a letter, and is composed of letters, numbers, and underscores. There is a special variable called the anonymous variable which is represented simply by a question mark (?).

```
Example variable names:
  \$foo \$bar\_ \$f1o2o3

The following are not valid variables:
  foo \$\_foo \$1bar
```

2.2 Statements

These are conditional statements which give output as true or false only and are frequently used to constrain variables. They are of two types, comparison and evaluation statements.

Comparison statements are used to compare variables against constants:

```
Example comparisons:
```

```
\$a>1+3-4; //means that variable 'a' is always greater than 0
\$boo <= 5; // means that variable 'boo' is less than or equal to 5
Evaluation or eval statements are used to query the program for solutions:
boofar(\$s,\$d,7); //from all the possible matches in the program's
   //graph it returns various possible values for the pair s and d,
   //and constrains those values in their scope appropriately, as
   //defined by the block in which the statement is contained</pre>
```

2.3 Facts

Facts are terminal nodes of the solution search which are always true. Facts help us define constant information in the program like the position of a wall.

2.4 Rules

Rules are similar to facts, but are only conditionally true. These conditions are defined inside a block. The defination or declaration of rules suggests that the solution tree is about to branch out to search for new solutions.

```
syntax: id(parameter1, parameter2....) {conditions}
```

The block is "conditions" in the above syntax. Block can be of 2 types, namely 'AND' and 'OR' block. AND blocks evalute true iff all the conditions inside the block are true. Similarly, the OR block is true if any one of the conditions is true. If no reduction method is specified (i.e. AND or OR is written), by default AND is used.

To define a OR block we use the following construct:

```
{OR:
    foo();
    bar();
}
```

The AND block is written similarly:

```
wall(2,3) {AND:
    foo();
    bar();
    {OR: barfoo(); foobar();}
}
```

Here "OR: barfoo(); foobar();" is a sub-block. wall(2,3) is true if foo() and bar() are true and if either of barfoo() or foobar() are true.

2.5 Directives

Three interpreter directives are supported; print, learn and forget. print is used to output strings and results during runtime. the learn and forget directives are used for database modification. They function similar to assert and retract of prolog.

```
Syntax: @directive_name(parameters);

Example:
    //prints "hello world: " then whatever constraints exist on $foo @print("hello world:", $foo);

    //adds a fact to the database that 'fire' is true for 4,5 @learn(fire(4,5););

    //erases the fact from the database that tree is true for 3,9. @forget(tree(3,9););
```

2.6 Simulator

Now for the user to be able to run a simulation or play a game in $C\mu$, they will have to use a simulator which interacts with the logic engine of the language to produce required results. For demonstration we have done so already. This simulator defines a class of games or simulations described as follows:

The environment is grid based and defined by a $C\mu LOG$ program. It potentially includes obstacles and a goals which the agent must reach, however the game is defined mostly by the environment program. Every object (i.e. agents, walls, switches, goals) in the environment is defined by grid positions. The environment specifies the representations of the entities to the simulator. The simulator re-evaluates the various object rules during each turn when it renders the grid, so the contents of the grid can be dynamically defined based on the state of the simulation or the contents of the program (which can be changed by the program.) For example based on the grid position of the agent the environment might remove or insert a wall. The agent program decides the next move based on previous moves and obstacle data.

The simulation of the agent program is also turn based. Each time the agent makes a move it sends its new coordinates to the simulator. The new coordinates become part of the simulation's state which are exposed to the environment when it is solved to render the scene.

```
Example 1:
  Size(5,5); //defines the grid size of 5 by 5
  wall(2,3); //a fact where wall is present at coordinates 2,3
  wall(4,2);
  goal(3,3); //a fact which defines the goal to be achieved by the player
  igo("UP"); //move($dir) would be true for all the values of $dir
              // for which igo($dir) is true
  move($dir){
        //causes the interpreter to remove igo("UP") from its database.
    @forget(igo($dir););
        //Fetch the next movement
    igo($dir);
 }
The output of the above program is:
X
. . . . .
. | # . .
x . . | .
. . . . .
```

In the above example, 'size', 'goal', 'wall' and 'move' are keywords for the simulator. Size(5,5) defines the grid in which walls (shown by the pipe symbol) are placed at coordinates (2,3) and (4,2). A goal object (shown by #) is placed at (3,3). The game simulation ends when the agent either hits a wall, moves out of the grid or reaches the goal.

In order to run code through the simulator, put your code in a file with a ".ul" extension (this extension is a convention only) then invoke the simulator, passing it the name of your code file:

```
./simulator mySimulation.ul
```

2.7 Program Modification

Now let us look at example using one of our program modification directives.

```
Example 2:
size(5, 5);
wall(2, 3);
wall(4,2);
```

```
goal(3, 3);
  imove("UP");
  imove("RIGHT");
  imove("RIGHT");
  imove("UP");
  move($dir) {
    @forget1( imove($dir); );
    imove($dir);
  }
OUTPUT:
  ==== Turn 1 ====
  . . . . .
  . . . . .
  . | # . .
  \mathbf{x} . . | .
  . . . . .
 x: Moving RIGHT
  ==== Turn 2 ====
  . . . . .
  . . . . .
  . | # . .
  . x . | .
  . . . . .
  x: Moving RIGHT
  ==== Turn 3 ====
  . . . . .
  . . . . .
  . | # . .
  . . x | .
  x: Moving UP
  Simulation over: x wins!!!Successfully reach the goal at position (3,3)
```

In the above code we see a carefully drafted route through the grid can make you win the game. Each step of the simulation is displayed. In this example, the 'imove' facts are used as a stack of moves which are queried for each turn, and removed from the stack after using it. The "@forget1" directive shown in this example removes only one fact from the program instead of all the facts which match the pattern.

2.8 Breakout

Although we can define an agent's actions within the environment program, it is typically more desirable to specify a separate agent file so that multiple agents can operate in the same environment. In the next example, we use a separate agent which queries the environment for the movements it should take—sort of like asking for directions.

```
Environment Program:
  size(10, 10);
  wall(?, 7);
  goal(6, 6);
  imove("UP");
  imove("RIGHT");
  imove("RIGHT");
  imove("RIGHT");
  imove("RIGHT");
  imove("RIGHT");
  agent("d", "tests/agents/delg_to_env.ul");
Agent Program:
  move($dir) {
    @print($e, " says move ", $dir);
    $e.@forget( imove($dir) );
    env($e);
    $e.imove($dir);
  }
```

```

3.2 Facts

Facts define factual relationships. They have a very similar syntax to rules, except they have no code block to make them conditionally true. Any query which matches a fact is simply true. Another way to think of facts is as terminal nodes in the solution search.

Each fact is composed of a name, and a comma separated list of parameters, each of which may be a constant, or a variable. Using any variable except the anonymous variable doesn't make much sense in a fact, but is allowable.

```
Example:
```

```
foo(4, symA); //Foo of 4 and symA is always true
foo(4, symA, ?); //Foo of 4, symA, and anything (wildcard) is always true
wall(4, 5); //In an environment might mean: there is a wall present at (4,5)

Grammar:
Fact -> Identifier ( ParamList );
ParamList -> Param | ParamList , Param
Param -> Variable | Number | String | Identifier
```

3.3 Rules

Rules define relationships which are conditionally true. They are similar to facts, but instead of ending with a semicolon, they contain have a block, which defines the conditions upon which the rule should be evaluated as true. Another way to think of a rules is as a node in the solution search which may branch, or be a leaf, depending on the contents of the condition block. Each rule is composed of a name, a comma separated list of parameters, and a block.

```
Example:
  foo(4) { bar(5); } //Foo of 4 is true if bar(5) is true
  foo(4) { bar(6); } //Foo of 4 is true if bar(6) is true
The two above rules are together equivalent to:
  foo(4) {OR: bar(5); bar(6); }

Grammar:
  Fact -> Identifier ( ParamList ) Block
```

3.4 Variables

Variables represent a value to be solved for. During rule matching, they will match any value or type, but can be constrained in an associated block. All variables are scoped to the rule, so that variable solutions can be shared between subblocks. Variables are represented by a dollar sign (\$) then the variable name. The name must start with a letter, and is composed of letters, numbers, and underscores. There is a special variable called the anonymous variable which is represented simply by a question mark (?). It cannot be referenced in the block, and simply matches anything.

```
Example:
  foo($X, $y, $foo_bar, $bar9, ?) { }

Grammar:
  Variable -> $[a-zA-Z][a-zA-Z0-9_]* | ?
```

3.5 Blocks

Blocks contain a list of statements (conditions) to determine truth, and specify a reduction method for those statements. Each block will reduce all of its statements using the same reduction method (usually AND or OR), but may contain sub-blocks. If the reduction method is omitted, AND is assumed. The syntax allows for other reduction methods to be allowed (such as xor, or a user-specified method), however the language does not yet support this.

```
Examples:
     foo();
     bar();
```

```
}
//True if foo and bar are both true.

{AND:
    foo();
    bar();
}
//True if foo and bar are both true.

{OR:
    foo();
    bar();
}
//True if foo or bar are true.

Grammar:
Block -> { (Identifer:)? StatementList }
StatementList -> Statement | StatementList Statement
```

3.6 Statements

Statements are boolean qualifiers which are used inside of blocks. They can be any one of three types: comparisons, evaluations, or blocks. Comparisons are used to constrain variables. Only values of the same type can be compared, and certain comparisons only work on certain types, so comparisons can be used to constrain variables by type. Evals are used to query the program, and have a similar syntax as facts. They can be thought of as a branch in the solution search. Blocks are considered a statement to support sub-blocks. They are evaluated and the reduced result is used. Comparisons and evals are both terminated by semicolons.

```
Examples:
```

```
1 < $X <= $Y < 10;  // A comparison
  range($X, $Y, 7);  // An eval
  !range($X, $Y, 7);  // This must not evaluate to true
  {OR: $X > 10; $X < 0; }  //A sub-block with two binary comparisons

Grammar:
  Statement -> Block | Eval ; | Comparison ;
  Eval -> (!)? Identifier ( ExprList );
  ExprList -> Expression | ExprList , Expression
  Comparison -> Expression ComparisonOp Expression | Expression ComparisonOp -> EQ | NEQ | LT | LEQ | GT | GEQ
```

3.7 Comparisons

Expressions are used to constrain variables. One side of the comparison must be a variable, and the other a constant. Depending on the type of the constant, only certain comparisons are allowed.

```
Examples:
    $r < 10;    // a comparison

Grammar:
    Comparison -> Expression CompOp Expression
    CompOp -> EQ | LT | LEQ | GT | GEQ
    Expression -> Number | String | Variable | Expression Op Expression | ( Expression )
```

3.8 Types

The following types are supported: integers, strings, symbols, and entities. Strings in $C\mu LOG$ are currently atomic, so no string processing such as splitting, joining, or searching is supported. They are primarily used for interaction with the rest of the system (printing, specifying files, ect.). Symbols are simply identifiers and can only be compared with equals. Entities are used to represent other programs (typically agents) and are used for interaction. In addition to equals and not equals comparison operators, they support the dot operator for interaction (discussed later.)

3.9 Directives

 $C\mu LOG$ supports a special syntax for interpreter directives. This allows programs to interact with the interpreter while avoiding symbol collisions. The syntax is similar to that of a fact's, but an at sign (@) is prepended. Three directives are currently supported: print, learn, and forget. Print is used to output strings, and results of searches during runtime. Learn and forget are discussed in the next section.

```
Examples:
    @print("Hello, world!");

Grammar:
    Directive -> @ Identifier ( ParamList );
```

Op -> PLUS | MINUS | TIMES | DIVIDE

3.10 Program Modification

The two directives learn and forget are used to modify a program at runtime. This is the only way in which $C\mu LOG$ supports non-volatile storage. Learn is used to add a fact to a program, and forget is used to remove a fact. The synatax for these two directives is special, consisting of the usual directive syntax, except contained inside the parenthesis is a fact definition. Any non-anonymous variables in this fact definition are filled in with solutions found for those variables, and the learn or forget is "executed" once for each solution. They are similar to Prolog's assert and retract.

Examples: @learn(wall(4,5);); //Remember that there is a wall at (4,5) @forget(agent(8, 10);); //Forget about the agent at (8, 10) Grammar: Directive -> @ (learn|forget) (Fact List);

3.11 Interaction- The Dot Operator

If a variable or symbol represents another program (entity), then it supports the dot operator. After appending a dot (.) to the reference, one can put an eval, a learn, or a forget, and that action will take place in the other entity's namespace. This can be used to ask for information from another program (such as the environment program or another agent) or to modify the other program–perhaps to teach another agent, to trick a competitor, or to change the operating environment. Future versions of $C\mu LOG$ could likely support some sort of access rules in the destination program, allowing it to control who is allowed to access what data, and who is allowed to change its program, and how. These access rules could potentially modify any queries or changes, perhaps revealing an entirely fake namespace to the other agent. Such access rules are beyond the scope of $C\mu LOG$ initially, however.

Example:

```
$agent.@learn( wall(4,5); ); //Tell agent2 that there is a wall at (4,5)
env.view($X, $Y, $obj); //Query the environment, find out what is at ($X, $Y)

Grammar:
DotOp -> Directive | Statement
Dot -> Variable . DotOp | Identifier . DotOp
```

4 Project Plan

We're cowboys—we don't have a friggin' plan!

4.1 Responsibilities

It was the responsibility of each team member to complete and help complete the individual parts of the interpreter. Specifically, initially the scanner and parser were developed by Devesh Dedhia and Nishant Shah. The AST file was done by Cheng Cheng. The interpreter and translator were completed by John Demme. Nishant Shah and Cheng Cheng developed the simulator together. Testing each phase and testing the whole system was not assigned to any particular person as it requires as much man power as available. Testing was done by every group member.

4.2 Timeline

The following were the timelines we decided on at the start of the semester:

Table 1: Project Deadlines

| Language Features design | Oct 20 |
|--------------------------|--------|
| LRM | Oct 22 |
| Scanner/Parser | Nov 5 |
| Translator | Nov 15 |
| Interpreter | Nov 22 |
| Simulator | Nov 27 |
| Cold Freeze | Dec 12 |
| Testing | Dec 18 |

As we started working on the project, it was soon realized that the above deadline are not what our aim should be as, it is not a start-end process. The development process was more like evolution. So every section was up and running by Nov 15th, i.e. by then we were able to print "hello world" in our language. After that we have been adding features and for that support is needed on every level, including the scanner, parser, ast file, translator, interpreter and the simulator. All members have been simultaneously working on the development and also testing the features at the same time.

4.3 Software Development Environment

The project will be developed on Ubuntu using Objective Caml 3.1.0. The scanner was developed using Ocamllex v3.1.0. The parser was developed using Ocamlyacc v3.1.0. We will use Python to run our tests and compare it with the expected output. Version control,managing multiple revisions of files, not only program source files, but any type of files is done using Subversion. We are using Google Code for issue tracking and Subversion hostin, plus Google groups("pltsim") for communicating within ourselves.

5 Architecture

The language $C\mu LOG$ we have designed will be used for communication between agents and an environment, as well as to determine behavior of said entities. Every agent program communicates with the environment program through a simulator. The simulator runs a $C\mu LOG$ logic solver and interpreter which functions on a set of rules and facts defined and modified by the environment and agents then provides solutions representing the actions to be taken by the agents.

The cmulog interpreter consists of several major blocks: scanner, parser, translator and interpreter. The relationship between these components is demonstrated in figure *. The simulator loads each program by reading in each necessary ".ul" file through the scanner and parser, resulting in an AST. The each AST is then passed into the interpreter, resulting in a database of rules and facts in the interpreter's internal format. The interpreter does not operator directly out of the AST, however: it uses the translator to convert the AST to a "translated synatax tree" (TST) first.

While the AST directly represents the structure of a $C\mu LOG$, there are a number of static transformations which do not change the meaning of the program, but make interpreting it much easier for the interpreter. The TST represents a simplier version of the program. The translator removes all the variable names and

Figure 1: Architecture Block Diagram

indexes them to a list and then each of them are identified by the number rather than the name. It also partitions all the statements with and without side-effects and runs all the ones without side-effects once for each solution. It performs all possible arithmetic to reduce each statement into its simplest form. It brings the unknown variable to the leftmost side by making all the necessary changes. For (3 + 4 > \$x - 1) will reduce to (\$x < 6). Lastly, all the static semantic checking is also done in the translator.

Using the database reference returned from the interpreter to the simulator, the simulator (or any other program for that matter) can query the database using the interpreter's "query" method, passing in the name to query, and the number of parameters. From this query method, the solution solver lazily evaluates the query by returning either "NoSolution" or "Solution". "NoSolution" indicates the all the results have already been returned. "Solution" is composed of a list of constraints (one per parameter) and a function to generate the next solution. Each solution is computed when the next function is called, so if there are an infinite number of solutions, the query function will not block forever. The caller may iterate through all of the solutions, or use only the first one.

Finally, the simulator uses the interpreter to query various terms for each turn, modifying its state and printing the output. For instance, it queries "wall" with two parameters (for each coordinate) each turn, iterates through all of the solutions, and puts a wall at each solution. For each agent, it queries the "move" term and uses only the first solution to move each agent. Before the first move, the simulator even queries the environment for the "agent" term to get the location of the agent program and its symbol!

Other programs such as the stand-alone "culog.ml" interpreter use the same interpreter interface to parse programs into databases and query these programs using different terms to invoke different behaviors. The stand-alone interpreter queries and "main" term and iterates through the results, and is generally used for testing of the interpreter. Other programs could use their own terms to generate different behaviors.

6 Test Plan

* Show two or three representative source language programs along with the target language program generated for each * Show the test suites used to test your translator * Explain why and how these test cases were chosen * What kind of automation was used in testing

A Appendix: Test Cases

Listing 51: $C\mu LOG$ Translated Syntax Tree

```
1
      This is a simpler, much more restrictive version of the AST.
2
      It is much easier for the interpreter to deal with, and is relatively
3
      easy to obtain given an AST. The trans.ml module translates from the AST
4
      to this TST.
